Post dotcom bubble

QE
Standard mean-reversion

\[
\Delta X_t = \kappa_x (\mu - X_{t-1}) + \sigma_x \varepsilon_t
\]

\[\varepsilon_t | F_{t-1} \sim D(0, 1)\]

Is the AR(1) model of this type suitable for modeling interest rates or other highly persistent systems with long periods of directional moves?
How about adding a latent stochastic central tendency factor?

\[
\begin{align*}
\Delta X_t &= \kappa_x (\mu_t - X_{t-1}) + \sigma_x \varepsilon_t \\
\Delta \mu_t &= \kappa_\mu (\bar{\mu} - \mu_{t-1}) + \sigma_\mu \epsilon_t \\
\varepsilon_t | G_{t-1} &\sim D(0, 1)
\end{align*}
\]

Note: Adding a latent stochastic central tendency factor is an idea in Balduzzi, Das and Foresi (1998, *Review of Economics and Statistics*), because empirical evidence suggests that the short-term interest rate tends to move towards the long term interest rate.
Local-momentum with latent central tendency (LM-CTAR)

\[
\begin{align*}
\Delta X_t &= \kappa_X (\mu_t - X_{t-1}) + \omega (\bar{X}_{(t-1)|n} - X_{t-1}) + \sigma_X \epsilon_t \\
\Delta \mu_t &= \kappa_\mu (\bar{\mu} - \mu_{t-1}) + \sigma_\mu \epsilon_t \\
\bar{X}_{(t-1)|n} &= \sum_{i=t-n}^{t-1} b_{t-i} X_i \\
\epsilon_t | G_{t-1} &\sim D(0, 1), \ \epsilon_t | G_{t-1} &\sim D(0, 1)
\end{align*}
\]

where \( \sum_{i=1}^{n} b_i = 1 \) with \( b_i \geq 0 \) for \( i = 1, 2, \ldots, n \). \( \bar{X}_{(t-1)|n} \) is meant to be some sort of moving weighted sample mean.

(Note: Exponentially decaying weights with \( n \) being set to \( \infty \) lead to a 3-dimensional Markov system, i.e., \((X_t, \bar{X}_{t|\infty}, \mu_t)\), with one extra decaying parameter and an additional latent factor, \( \bar{X}_{t|\infty} \).)
Local-momentum without latent central tendency (LM-AR)

\[ \Delta X_t = \kappa_x (\bar{\mu} - X_{t-1}) + \omega (\bar{X}_{(t-1)|n} - X_{t-1}) + \sigma_x \varepsilon_t \]

\[ \bar{X}_{(t-1)|n} = \sum_{i=t-n}^{t-1} b_{t-i} X_i \]

\[ \varepsilon_t | \mathcal{G}_{t-1} \sim D(0, 1) \]
Interesting features

- Local momentum building: $\omega < 0$
- Local momentum preserving: $\omega > 0$

Basic properties

- Stationarity and ergodicity of LM-CTAR can be characterized by recognizing it as ARMA($n, \infty$). The spectral radius of the AR coefficient matrix less than 1 is both sufficient and necessary, because the MA($\infty$) coefficients are absolutely summable.
- Easy to verify sufficiency conditions are given in the paper.
LM-CTAR model in a matrix form

\[ X_t = A + BX_{t-1} + Z_t \]

\[
X_t = \begin{bmatrix}
X_t \\
X_{t-1} \\
\vdots \\
X_{t-n+1}
\end{bmatrix}
\]

\[
Z_t = \begin{bmatrix}
k_x(\mu_t - \bar{\mu}) + \sigma_x \varepsilon_t \\
0 \\
\vdots \\
0
\end{bmatrix}
\]

\[
A = \begin{bmatrix}
k_x \bar{\mu} \\
0 \\
\vdots \\
0
\end{bmatrix}
\]

\[
B = \begin{bmatrix}
1 - k_x - \omega(1 - b_1) & \omega b_2 & \ldots & \omega b_{n-1} & \omega b_n \\
1 & 0 & \ldots & 0 & 0 \\
0 & 1 & \ldots & 0 & 0 \\
\vdots & \vdots & \ddots & \vdots & \vdots \\
0 & 0 & \ldots & 1 & 0
\end{bmatrix}
\]
A simulated sample path for the LM-AR with 5 lags. The parameters are: $ar{\mu} = 0$, $\kappa_x = 0.001$, $\omega = -0.5$, $\sigma_x = 0.002$ and $\sigma_\mu = 0$. 
A simulated sample path for the LM-AR with 10 lags. The parameters are: $\bar{\mu} = 0, \kappa_x = 0.001, \omega = -0.2, \sigma_x = 0.02$ and $\sigma_\mu = 0$. 
Continuous-time LM-CTAR

\[ dX_t = [\kappa_x (\mu_t - X_t) + \omega (\bar{X}_t(\tau) - X_t)] \, dt + \sigma_x dW_{xt} \]

\[ d\mu_t = \kappa_\mu (\bar{\mu} - \mu_{t-1}) \, dt + \sigma_\mu dW_{\mu t} \]

\[ \bar{X}_t(\tau) = \int_{t-\tau}^{t} b(t-s)X_s \, ds \]

where \( \kappa_\mu > 0, \sigma_\mu > 0, \kappa_x \geq 0, \sigma_x > 0, \) and \( \int_0^\tau b(s) \, ds = 1 \) with \( b(s) \geq 0 \) for \( 0 \leq s \leq \tau \); and \( W_{xt} \) and \( W_{\mu t} \) are two independent Wiener processes.

(Note: Again exponentially decaying weights with \( n \) being set to \( \infty \) can lead to a 3-dimensional Markov system, i.e., \( (X_t, \bar{X}_t|_\infty, \mu_t) \), with one extra decaying parameter and an additional latent factor, \( \bar{X}_t|_\infty \).)
## US Treasury rates (constant maturity, continuously compounded)

Duan&Miao (NUS)  
Local-Momentum Autoregression ...  
(04/2015)
Using the weekly series of one interest rate (3-month)

![Table of parameters](image)

(Both versions of the local-momentum model use a 7-week moving-window average.)
A 3-factor term structure model

The base interest rate dynamic has two components: global driver \( (X_t) \) and local variation \( (v_t) \):

\[
   r_t = X_t + v_t
\]

(Note: The base rate is driven by 3 latent factors, because \( X_t \) is latent, \( X_t \)'s central tendency is also latent, and \( v_t \) is latent.)

The local variation is a standard AR(1) process:

\[
   \Delta v_t = -\kappa_v v_{t-1} + \sigma_v \xi_t \\
   \xi_t | (\mathcal{G}_t \cup v_{t-1}) \sim N(0, 1)
\]

where \( 0 < \kappa_v < 2 \), and \( (\mathcal{G}_t \cup v_{t-1}) \) denotes the minimum \( \sigma \)-algebra generated by \( \mathcal{G}_t \) and \( v_{t-1} \).
The 3-factor model in a matrix form

\[ r_t = H'X_t^* \]
\[ SX_t^* = C + DX_{t-1}^* + W_t \]

where

\[
H = \begin{bmatrix}
1 & 0 \\
0_{n-1} & 0 \\
0 & 1
\end{bmatrix}
\]
\[
X_t^* = \begin{bmatrix}
X_t \\
\mu_t - \bar{\mu} \\
v_t
\end{bmatrix}
\]
\[
W_t = \begin{bmatrix}
\sigma_x \varepsilon_t \\
0_{n-1} \\
\sigma_\mu \varepsilon_t \\
\sigma_v \xi_t
\end{bmatrix}
\]
\[
C = \begin{bmatrix}
A \\
0 \\
0
\end{bmatrix}
\]
\[
D = \begin{bmatrix}
B & 0 & 0 \\
0 & 1 - \kappa_\mu & 0 \\
0 & 0 & 1 - \kappa_v
\end{bmatrix}
\]
\[
S = \begin{bmatrix}
1 & 0 & -\kappa_x & 0 \\
0 & I_{(n-1) \times (n-1)} & 0 & 0 \\
0 & 0 & 1 & 0 \\
0 & 0 & 0 & 1
\end{bmatrix}
\]
\[
U = \begin{bmatrix}
\sigma_x^2 & 0 & 0 & 0 \\
0 & \sigma_x^2_{(n-1) \times (n-1)} & 0 & 0 \\
0 & 0 & \sigma_\mu^2 & 0 \\
0 & 0 & 0 & \sigma_v^2
\end{bmatrix}
\]

Note: \( U \) is the covariance matrix for \( W_t \), and \( X_t, A \) and \( B \) have been previously defined.
Stochastic discount factor and term structure

$h$: the length of one period measured as the fraction of a year. The stochastic discount factor from time $t + \tau$ back to time $t$ is assumed to be $\exp[-r_t(\tau) \tau h] M_{t,t+\tau}$ where for $s \geq t$,

$$M_{t,s} = \alpha(t, s) \exp\left\{ \sum_{j=t+1}^{s} (\lambda_0 + \lambda_1 X_{j-1}) \epsilon_j + (\psi_{\mu 0} + \psi_{\mu 1} \mu_{j-1}) \epsilon_j \right. + (\psi_{v 0} + \psi_{v 1} V_{j-1}) \xi_j \left\}$$

Note that $\alpha(t, s)$ is the factor that makes $M_{t,s}$ a martingale for $s \geq t$.

Define a martingale measure $Q_{t,T}$ by setting $dQ_{t,T}/dP = M_{t,T}$. 
Forward and spot interest rates

\( f_t(\tau) \): the one-period forward rate at time \( t \) starting at time \( t + \tau \), where each of the \( \tau \) periods is of length \( h \). \( \mathcal{H}_t \): the filtration generated by \( \{(X_s, \mu_s, \nu_s); s \leq t\} \). It follows that, for \( \tau \geq 1 \),

\[
    f_t(\tau) = -\frac{\ln E^Q(e^{-r_{t+\tau}h}|\mathcal{H}_t)}{h}
\]

Note: The base interest rate \( r_t \) equals \( f_t(0) \).

Forward rates for different forward starting times can in turn be used to compute spot interest rate rates such as, for \( \tau \geq 1 \),

\[
    r_t(\tau) = \frac{1}{\tau} \sum_{j=0}^{\tau-1} f_t(j).
\]
Risk-neutral system

\[ r_t = H'X_t^* \]

\[ SX_t^* = C^* + D^*X_{t-1} + W_t^* \]

where

\[ C^* = \begin{bmatrix} \kappa x \bar{\mu} + \sigma_x \lambda_0 \\ 0_{n-1} \\ \sigma_{\mu} \psi_{\mu_0} \\ \sigma_{\psi} \psi_0 \end{bmatrix} \quad W_t^* = \begin{bmatrix} \sigma_x \epsilon_t^Q \\ 0_{n-1} \\ \sigma_{\mu} \epsilon_t^Q \\ \sigma_{\psi} \psi_t^Q \end{bmatrix} \]

\[ D^* = \begin{bmatrix} d & \omega b_2 & \ldots & \omega b_{n-1} & \omega b_n & 0 & 0 \\ 1 & 0 & \ldots & 0 & 0 & 0 & 0 \\ 0 & 1 & \ldots & 0 & 0 & 0 & 0 \\ \vdots & \vdots & \ldots & \vdots & \vdots & \vdots & \vdots \\ 0 & 0 & \ldots & 1 & 0 & 0 & 0 \\ 0 & 0 & \ldots & 0 & 0 & 1 - \kappa_\mu + \sigma_{\mu} \psi_{\mu 1} & 0 \\ 0 & 0 & \ldots & 0 & 0 & 0 & 1 - \kappa_v + \sigma_{\psi} \psi_{v 1} \end{bmatrix} \]

and \( d = 1 - \kappa x - \omega (1 - b_1) + \sigma_x \lambda_1. \)
The term structure formula

For $\tau \geq 1$,

$$r_t(\tau) = \Phi_1(\tau) + \Phi_2(\tau)X_t^*$$

where

$$\Phi_1(\tau) = H'(I - S^{-1}D^*)^{-1} \left( I - \frac{1}{\tau} \sum_{j=0}^{\tau-1} (S^{-1}D^*)^j \right) S^{-1}C^*$$

$$\Phi_2(\tau) = H' \left( \frac{1}{2\tau} \sum_{j=0}^{\tau-1} \sum_{i=0}^{j-1} (S^{-1}D^*)^i S^{-1}U(S^{-1})'[(S^{-1}D^*)^i]' \right) H$$
Estimation by the Kalman filter

Facing yields of several maturities gives rise to the measurement equations:

\[
\begin{align*}
\tilde{r}_t(\tau_1) &= \Phi_1(\tau_1) + \Phi_2(\tau_1)X_t^* + \epsilon_{1t} \\
\tilde{r}_t(\tau_2) &= \Phi_1(\tau_2) + \Phi_2(\tau_2)X_t^* + \epsilon_{1t} \\
&\vdots \\
\tilde{r}_t(\tau_k) &= \Phi_1(\tau_k) + \Phi_2(\tau_k)X_t^* + \epsilon_{kt}
\end{align*}
\]

The number of identifiable parameters

The three latent factor processes are governed by eight parameters under the physical probability, i.e., \(\{\bar{\mu}, \kappa_x, \omega, \sigma_x, \kappa_\mu, \sigma_\mu, \kappa_v, \sigma_v\}\). There are six parameters arising from risk-neutralization, i.e., \(\{\lambda_0, \lambda_1, \psi_{\mu_0}, \psi_{\mu_1}, \psi_{v0}, \psi_{v1}\}\), but there is only one identifiable parameter among \(\lambda_0, \psi_{\mu_0}\) and \(\psi_{v0}\) because these three enter into the same constant in the risk neutral system.

The filtered central tendency estimates corresponding to two versions of the 3-factor Gaussian term structure model built on, respectively, the CTAR and LM-CTAR processes from January 4, 1954 to December 31, 2013 on a weekly frequency. Also plotted is the 20-year US Treasury yields (continuously compounded) when they were available. The vertical axis is in percentage points.
Does it make sense to define regimes as high, average and low rates (or volatilities)? Can one conduct monetary easing while in the low-rate regime?

How about classifying interest rate regimes as Status Quo, Monetary Easing and Monetary Tightening? Entering Quantitative Easing (QE) is “Monetary Easing” and staying in QE will be “Status Quo”.

In terms of the local-momentum model, “Status Quo” means using the current parameter values, and entering “Monetary Easing (Tightening)” state means subtracting (adding) a positive constant from (to) $\bar{\mu}$, and this can be done repeatedly. In addition, the local-momentum parameter $\omega$ can also be regime-specific.
